1 Ranking and unranking Dyck paths

1.1 Dyck paths to words

Recall Dyck paths from lecture 5

We can represent a Dyck path as a word using the letters $\{↗, ↘\}$. If we write $↗$ as 0 and $↘$ as 1 we can represent a Dyck path as a binary string.

Which binary strings do we get?

Definition. Say a binary string of length $2n$ is **totally balanced** if

- The string contains n zeros and n ones.
- For any $1 \leq i \leq 2n$, the first i elements of the string include at least as many zeros and ones.

This is exactly the same as the condition defining Dyck paths: the second point is that the path never goes strictly below the x -axis, while the first point is that the path returns to the x -axis at the end.

Viewing Dyck paths as binary strings gives them a natural lexicographic order. This is the order we will rank and unrank with respect to.

1.2 Counting suffixes of Dyck paths

Definition. Let $D_{2n}(x, y)$ be the set of paths from (x, y) to $(2n, 0)$ using the steps $(1, 1)$ and $(1, -1)$ and which never go strictly below the x -axis.

Let $d_{2n}(x, y) = |D_{2n}(x, y)|$.

Such paths are ends (suffixes if you think of them as words) of Dyck paths.

Proposition. Let x, y , and n be positive integers with $x + y$ even and $x + y \leq 2n$. Then

$$d_{2n} = \binom{2n - x}{n - \frac{x+y}{2}} - \binom{2n - x}{n - 1 - \frac{x+y}{2}}$$

Proof. Lets first count all paths using the steps $(1, 1)$ and $(1, -1)$ which go from (x, x) to $(2n, 0)$ without regards to whether or not they cross the x -axis.

Such paths must contain $2n - x$ steps, since they need to move $2n - x$ units in the x direction. Furthermore such paths must move a net of y steps in the y direction. So there are y extra $(1, -1)$ steps, and the remaining steps are evenly divided between $(1, 1)$ and $(1, -1)$. So there are $2n - x - y$ such remaining steps, half of each type. Thus there are

$$n - \frac{x+y}{2} (1, 1) \text{ steps}$$

$$n - \frac{x+y}{2} + y (1, -1) \text{ steps}$$

and no restriction on which order the steps come in. So there are

$$\binom{2n-x}{n-\frac{x+y}{2}}$$

such paths.

Now we just need to subtract off those paths which do go strictly below the x axis. Let w be such a path, and let $(a, -1)$ be the integer point where it is first strictly below the x -axis. Flip the portion of the path before $(a, -1)$ across the line $y = -1$, as illustrated

Note that the modified path goes from $(x, -y - 2)$ to $(2n, 0)$. Note also that given a path from $(x, -y - 2)$ to $(2n, 0)$ there is a unique point where it may have been flipped according to this rule: namely the first place where the path reaches $(a, -1)$ for some a .

Thus the number of paths from (x, y) to $(2n, 0)$ which do go strictly below the x -axis is the same as the number of all paths from $(x, -y - 2)$ to $(2n, 0)$. Counting as before this is

$$\binom{2n-x}{n-1-\frac{x+y}{2}}$$

Therefore the number of paths from (x, y) to $(2n, 0)$ which never go strictly below the x -axis is

$$\binom{2n-x}{n-\frac{x+y}{2}} - \binom{2n-x}{n-1-\frac{x+y}{2}}$$

□

1.3 Ranking and unranking

The formula for counting suffixes tells us about the rank. Suppose $w = w_1w_2 \cdots w_{2n}$ is a Dyck path represented as a binary string. Suppose that after the first k steps the path is at the point (x, y) . If $w_{k+1} = 1$ so the next step is down, then all the words which begin $w_1w_2 \cdots w_k0$ come before w in lexicographic order. There are $d_{2n}(x+1, y+1)$ such paths (the $+1$ s come from the last up step). Thus we have

```

Algorithm: RankDyck
input: n, w.  w is a totally balanced word of length 2n
y=0
r=0
for x from 1 to 2n
  if w(x) = 0
    y=y+1
  else
    r=r+binom(2n-x, n-(x+y)/2)-binom(2n-x, n-1-(x+y)/2)
    y=y-1
output: r

```

```

Algorithm: UnrankDyck
input: n, r.
y=0
r_low=0
for x from 1 to 2n
  m = binom(2n-x, n-(x+y)/2)-binom(2n-x, n-1-(x+y)/2)
  if r <= r_low + m - 1
    y=y+1
    w(x)=0
  else
    r_low = r_low + m
    y=y-1
    w(x)=1
output: w

```

Here's an example of each algorithm which comes from Kreher and Stinson, *Combinatorial Algorithms*, section 3.4.

Suppose we want to compute $rank(w = 0010110101)$. Then:

x	$w(x)$	y	r
1	0	1	0
2	0	2	0
3	1	1	14
4	0	2	14
5	1	1	18
6	1	0	21
7	0	1	21
8	1	0	22
9	0	1	22
10	1	0	

so the rank is 22.

Now to calculate $unrank(22)$

m	x	y	r_{low}	$w(x)$
$d_{10}(1,1) = 42$	1	1	0	0
$d_{10}(2,2) = 28$	2	2	0	0
$d_{10}(3,3) = 14$	3	1	14	1
$d_{10}(4,2) = 9$	4	2	14	0
$d_{10}(5,3) = 4$	5	1	18	1
$d_{10}(6,2) = 3$	6	0	21	1
$d_{10}(7,1) = 2$	7	1	21	0
$d_{10}(8,2) = 1$	8	0	22	1
$d_{10}(9,1) = 1$	9	1	22	0
$d_{10}(10,2) = 0$	10	0	22	1

so we unrank to 0010110101 as expected.
