What about the antipode.

Proposition.

- (a) $S(p_n) = -p_n$
- (b) $S(e_n) = (-1)^n h_n$
- (c) $S(h_n) = (-1)^n e_n$

Recall the fundamental involution $\omega : \Lambda \rightarrow \Lambda : e_n \mapsto h_n, \omega \circ \omega = id$.

Proof of Proposition.

(a) From the fact that p_n are primitive.

(b, c) Recall from last time we had $\Delta e_n = \sum_{i+j=n} e_i \otimes e_j$ and $\Delta h_n = \sum_{i+j=n} h_i \otimes h_j$ so we also have $S * id =$

$u \circ \epsilon = id * S$ applied to e_n . $\sum_{i+j=n} S(e_i)e_j = \delta_{0,n} = \sum_{i+j=n} e_i S(e_j)$ where

$$\delta_{ij} = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$$

is the dirac delta function. Likewise $\sum_{i+j=n} S(h_i)h_j = \delta_{n,0} = \sum_{i+j=n} h_i S(h_j)$. From the fundamental involution

$\sum_{i+j=n} (-1)^i e_i h_j = \delta_{0,n}$ so by induction or independence $S(h_i) = (-1)^i e_i$. Then since ω is an involution, we

also get $S(e_i) = (-1)^i h_i$.

cor $S(f) = (-1)^n \omega(f) \forall f \in \Lambda_n$.

Robinson-Schensted Algorithm

Definition. A (standard) Young tableau of shape λ , λ a partition of n is a filling of the Ferrer's diagram of λ with $\{1, 2, \dots, n\}$ and strictly increasing along rows and columns.

ex $\lambda = (4, 2, 1), n = 7$.

1	3	4	7
2	5		
6			

Theorem.

There is a bijection between permutations of $\{1, \dots, n\}$ and pairs of Young tableaux of the same shape λ where λ is a partition of n . The bijection is given by an algorithm.

Definition.

Given a tableau T with distinct entries and i not in T , then the procedure to insert i into T is as follows. To begin the current row is the top row of T .

- find the smallest $j > i$ in current row if it exists
- if no such j exists put a new box at the end of the current row and put i in it. STOP.
- otherwise put i where j was and continue with the next row down as the current row and j as i .

ex

T	i									
<table border="1" style="border-collapse: collapse; text-align: center;"> <tr><td>2</td><td>5</td><td>6</td></tr> <tr><td>7</td><td>8</td><td></td></tr> </table>	2	5	6	7	8		← 3			
2	5	6								
7	8									
<table border="1" style="border-collapse: collapse; text-align: center;"> <tr><td>2</td><td>3</td><td>6</td></tr> <tr><td>7</td><td>8</td><td></td></tr> </table>	2	3	6	7	8		← 5			
2	3	6								
7	8									
<table border="1" style="border-collapse: collapse; text-align: center;"> <tr><td>2</td><td>3</td><td>6</td></tr> <tr><td>5</td><td>8</td><td></td></tr> </table>	2	3	6	5	8		← 7			
2	3	6								
5	8									
<table border="1" style="border-collapse: collapse; text-align: center;"> <tr><td>2</td><td>3</td><td>6</td></tr> <tr><td>5</td><td>8</td><td></td></tr> <tr><td>7</td><td></td><td></td></tr> </table>	2	3	6	5	8		7			
2	3	6								
5	8									
7										

is the result of the procedure. Observe that the procedure terminates because each time through we go down a row, but there are only finitely many nonempty rows. So if I don't stop sooner in a finite length of time, I'll reach an empty row at which point I will necessarily arrive at bullet 2 and so terminate.

Robinson Schensted Algorithm.

Input σ a permutation of $\{1, \dots, n\}$

Set P_0, Q_0 empty tableaux

for i from 1 to n

· insert $\sigma(i)$ into P_{i-1} , call the result P_i

· P_i differs in shape from P_{i-1} in exactly one added box. Take Q_{i-1} add a box in that position, put i in it and call the result Q_i .

Output P_n and Q_n .

ex

Write the permutation in 2-line notation

$$L = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ 5 & 7 & 2 & 8 & 6 & 1 & 4 & 3 & 9 \end{pmatrix}$$

i	$\sigma(i)$	P_i	Q_i
1	5	$\boxed{5}$	$\boxed{1}$
2	7	$\boxed{5} \boxed{7}$	$\boxed{1} \boxed{2}$
3	2	$\begin{array}{ c c } \hline \boxed{2} & \boxed{7} \\ \hline \boxed{5} & \end{array}$	$\begin{array}{ c c } \hline \boxed{1} & \boxed{2} \\ \hline \boxed{3} & \end{array}$
4	8	$\begin{array}{ c c c } \hline \boxed{2} & \boxed{7} & \boxed{8} \\ \hline \boxed{5} & & \end{array}$	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{2} & \boxed{4} \\ \hline \boxed{3} & & \end{array}$
5	6	$\begin{array}{ c c c } \hline \boxed{2} & \boxed{6} & \boxed{8} \\ \hline \boxed{5} & \boxed{7} & \end{array}$	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{2} & \boxed{4} \\ \hline \boxed{3} & \boxed{5} & \end{array}$
6	1	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{6} & \boxed{8} \\ \hline \boxed{2} & \boxed{7} & \\ \hline \boxed{5} & & \end{array}$	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{2} & \boxed{4} \\ \hline \boxed{3} & \boxed{5} & \\ \hline \boxed{6} & & \end{array}$
7	4	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{4} & \boxed{8} \\ \hline \boxed{2} & \boxed{6} & \\ \hline \boxed{5} & \boxed{7} & \end{array}$	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{2} & \boxed{4} \\ \hline \boxed{3} & \boxed{5} & \\ \hline \boxed{6} & \boxed{7} & \end{array}$
8	3	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{3} & \boxed{8} \\ \hline \boxed{2} & \boxed{4} & \\ \hline \boxed{5} & \boxed{6} & \\ \hline \boxed{7} & & \end{array}$	$\begin{array}{ c c c } \hline \boxed{1} & \boxed{2} & \boxed{4} \\ \hline \boxed{3} & \boxed{5} & \\ \hline \boxed{6} & \boxed{7} & \\ \hline \boxed{8} & & \end{array}$
9	9	$\begin{array}{ c c c c } \hline \boxed{1} & \boxed{3} & \boxed{8} & \boxed{9} \\ \hline \boxed{2} & \boxed{4} & & \\ \hline \boxed{5} & \boxed{6} & & \\ \hline \boxed{7} & & & \end{array}$	$\begin{array}{ c c c c } \hline \boxed{1} & \boxed{2} & \boxed{4} & \boxed{9} \\ \hline \boxed{3} & \boxed{5} & & \\ \hline \boxed{6} & \boxed{7} & & \\ \hline \boxed{8} & & & \end{array}$

Observe P_i and Q_i are always the same shape by induction. Also each time through the for loop adds a box to P_i and Q_i so P_n, Q_n each contain n boxes. Next we want to show that insertion maintains the tableau property.

In the bump case $j > i$ but the smallest such j in the row so by distinctness i is larger than everything preceding j in the row and by choice of j is smaller than everything after.

Now consider the columns in the bump case.

	a	
$< i$	j	
	$> j$	

Any element below j is $> j$ and hence $> i$ so no problem. If we are in first row, no problem. Otherwise i came from bumping in the row above. i could not have been in a column to the left of j because in j 's row all elements to the left of j are $< i$ by the above paragraph. So either i was above j or something $< i$ was above j . When it is bumped something smaller goes in its place so after that the element above j is $< i$.

Next consider the case when a box is added to a row. In this case the nonstrictness is maintained as no element in the row is $> j$ and elements are distinct. Consider the columns, if we're in the top row then done. Otherwise we need to make sure that there is a box above the new box and it contains something $< i$. But to have gotten to this point i must have been bumped from the row above but i can't have been above anything in the current row since those elements are $< i$. So either i was above the new box or something

$< i$ was. But i was bumped by something less than itself so after bumping something $< i$ is above the new box. So the tableau property is maintained so by induction each P_i is a tableau. The Q_i are also tableau since at each stage I add a new box at the end of a row or begin a new row and put a larger number in. It remains to show this is a bijection. We can do so by showing it's reversible.

7			

Q

1	2	4	9
3	5		
6	7		
8			

Here's how to reverse a step give P_i, Q_i .

Find the largest element k in P_i . Find the matching box in Q_i , call the entry in the box l . Remove l from Q_i to get Q_{i-1} . Uninsert l from P_i to get P_{i-1} . The entry which pops out is l' then $k \mapsto l'$ in the permutation. Continuing the example

	P_i	Q_i																								
$7 \rightarrow 6$	<table border="1" style="border-collapse: collapse;"> <tr><td>1</td><td>3</td><td>8</td></tr> <tr><td>2</td><td>4</td><td></td></tr> <tr><td>5</td><td>6</td><td></td></tr> <tr><td>7</td><td></td><td></td></tr> </table>	1	3	8	2	4		5	6		7			<table border="1" style="border-collapse: collapse;"> <tr><td>1</td><td>2</td><td>4</td></tr> <tr><td>3</td><td>5</td><td></td></tr> <tr><td>6</td><td>7</td><td></td></tr> <tr><td>8</td><td></td><td></td></tr> </table>	1	2	4	3	5		6	7		8

5	7																									
$4 \rightarrow 3$	<table border="1" style="border-collapse: collapse;"> <tr><td>1</td><td>3</td><td>8</td></tr> <tr><td>2</td><td>6</td><td></td></tr> <tr><td>5</td><td>7</td><td></td></tr> </table>	1	3	8	2	6		5	7																	
1	3	8																								
2	6																									
5	7																									
3 leaves	<table border="1" style="border-collapse: collapse;"> <tr><td>1</td><td>4</td><td>8</td></tr> <tr><td>2</td><td>6</td><td></td></tr> <tr><td>5</td><td>7</td><td></td></tr> </table>	1	4	8	2	6		5	7																	
1	4	8																								
2	6																									
5	7																									

How to uninsert j

- remove j and its box
- in the row above find the largest entry $i, i < j$ (always exist if there is a row) replace i by j .
- now do the same in the row above with i in place of j

When we process the top row the entry we find is the l' which pops out.

The inverse

1	2	3	4	5	6	7	8	9
6	8	3	7	1	5	2	4	9

1	2	4	9	1	3	8	9
3	5			2	4		
6	7			5	6		
8				7			

Note P and Q are switched. This is true in general but requires another

construction.

One way to view a permutation is as a permutation matrix.

ex

$$\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \longleftrightarrow \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}$$

Permutation matrices are matrices with exactly one 1 in each row and exactly one 1 in each column and rest are 0's. Instead consider matrices with all nonnegative integer entries.

$$\text{ex} \begin{pmatrix} 1 & 0 & 2 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{pmatrix}$$

Convert to a list of pairs as before: if the (i, j) th entry is k , put k copies of $\begin{bmatrix} i \\ j \end{bmatrix}$ in the list ordered lexicographically (i.e. ordered first by top entry and among pairs with the same top entry, ordered by bottom entries). This example yields

$$\begin{bmatrix} 1 & 1 & 1 & 2 & 2 & 3 & 3 \\ 1 & 3 & 3 & 2 & 2 & 1 & 3 \end{bmatrix}$$

Next time we'll prove

Theorem.

There is a bijection between lists of ordered pairs of positive integers ordered lexicographically, length of list is n and pairs of semistandard Young tableaux of the same shape λ where λ is a partition of n .
